EXP NO: 2a DATE:

RSA ALGORITHM

AIM:

To write a python program to implement RSA Algorithm.

ALGORITHM:

- 1. Select two large prime numbers, p and q.
- 2. Multiply these numbers to find $n = p \times q$, where n is called the modulus for encryption and decryption.
- 3. Choose a number e less than n, such that n is relatively prime to $(p 1) \times (q 1)$. It means that e and $(p 1) \times (q 1)$ have no common factor except 1. Choose "e" such that $1 \le e \le \phi(n)$, e is prime to $\phi(n)$, gcd (e,d(n)) = 1
- 4. If $n = p \times q$, then the public key is <e, n>. A plaintext message m is encrypted using public key <e, n>. To find ciphertext from the plain text following formula is used to get ciphertext C.

 $C = me \mod n$

- 5. Here, m must be less than n. A larger message (>n) is treated as a concatenation of messages, each of which is encrypted separately.
- 6. To determine the private key, we use the following formula to calculate the d such that:

De mod
$$\{(p-1) \ x \ (q-1)\} = 1$$

Or
De mod $\varphi(n) = 1$

7. The private key is <d, n>. A ciphertext message c is decrypted using private key <d, n>. To calculate plain text m from the ciphertext c following formula is used to get plain text m.

PROGRAM:

```
from math import gcd
```

```
# defining a function to perform RSA approch
def RSA(p: int, q: int, message: int):
  # calculating n
  n = p * q
  # calculating totient, t
  t = (p - 1) * (q - 1)
  # selecting public key, e
  for i in range(2, t):
     if gcd(i, t) == 1:
       e = i
       break
  # selecting private key, d
  j = 0
  while True:
    if (j * e) % t == 1:
       d = j
       break
    j += 1
  # performing encryption
  ct = (message ** e) % n
  print(f"Encrypted message is {ct}")
```

```
# performing decryption
mes = (ct ** d) % n
print(f"Decrypted message is {mes}")

p=int(input("Enter the value of p: "))
q=int(input("Enter the value of q: "))
msg=int(input("Enter the message: "))
RSA(p,q,msg)
```

OUTPUT:

```
(kali@ kali)-[~/Documents/cnslab]
$ vi rsa.py

(kali@ kali)-[~/Documents/cnslab]
$ python3 rsa.py
Enter the value of p: 11
Enter the value of q: 13
Enter the message: 475
Encrypted message is 84
```

RESULT:

Thus, a python program is implemented to demonstrate RSA Algorithm.

DIFFIE HELMAN KEY EXCHANGE

AIM:

To write a python program to Diffie Helman Key Exchange.

ALGORITHM:

- 1.Agree on Public Parameters: Both parties agree on two publicly known numbers: a large prime number $\langle (p \rangle)$ (the modulus) and a primitive root modulo $\langle (p \rangle)$, denoted as $\langle (g \rangle)$.
- 2. Generate Private Keys:
 - Each party independently selects a private key.
- Party A selects a private key \setminus (a \setminus), which is a randomly chosen integer within the range \setminus (1 < a < p-1 \setminus).
- Party B selects a private key \(b \), which is a randomly chosen integer within the range \((1 < b < p-1 \).
- 3. Compute Public Keys:
 - Party A computes its public key (A) using the formula $(A = g^a \mod p)$.
 - Party B computes its public key $\ (B \)$ using the formula $\ (B = g^b \)$.
- 4. Exchange Public Keys:
 - Party A sends its public key \(A \) to Party B.
 - Party B sends its public key \(B \) to Party A.
- 5. Compute Shared Secret:
- Party A uses Party B's public key \setminus (B \setminus) and its own private key \setminus (a \setminus) to compute the shared secret \setminus (s \setminus) using the formula \setminus (s = B^a \setminus mod p \setminus).
- Party B uses Party A's public key \setminus (A \setminus) and its own private key \setminus (b \setminus) to compute the shared secret \setminus (s \setminus) using the formula \setminus (s = A^b \setminus mod p \setminus).
- 6.Use Shared Secret: The shared secret \setminus (s \setminus) can be used as a key for symmetric encryption, allowing Party A and Party B to securely communicate.
- 7. Ensure Security**: The security of the Diffie-Hellman key exchange relies on the difficulty of solving the discrete logarithm problem. Therefore, $\langle (p \rangle) \rangle$ and $\langle (g \rangle) \rangle$ should be chosen such that they provide a high level of security against potential attacks.

PROGRAM:

```
def prime_checker(p):
       # Checks If the number entered is a Prime Number or not
       if p < 1:
               return -1
       elif p > 1:
               if p == 2:
                       return 1
               for i in range(2, p):
                       if p % i == 0:
                              return -1
                       return 1
def primitive_check(g, p, L):
       # Checks If The Entered Number Is A Primitive Root Or Not
       for i in range(1, p):
               L.append(pow(g, i) % p)
       for i in range(1, p):
               if L.count(i) > 1:
                       L.clear()
                       return -1
               return 1
1 = \lceil \rceil
while 1:
       P = int(input("Enter P : "))
       if prime_checker(P) == -1:
               print("Number Is Not Prime, Please Enter Again!")
               continue
       break
while 1:
       G = int(input(f"Enter The Primitive Root Of {P} : "))
       if primitive_check(G, P, l) == -1:
               print(f"Number Is Not A Primitive Root Of {P}, Please Try Again!")
               continue
       break
# Private Keys
x1, x2 = int(input("Enter The Private Key Of User 1:")), int(
       input("Enter The Private Key Of User 2:"))
```

```
while 1:
    if x1 >= P or x2 >= P:
        print(f"Private Key Of Both The Users Should Be Less Than {P}!")
        continue
    break
# Calculate Public Keys
y1, y2 = pow(G, x1) % P, pow(G, x2) % P
# Generate Secret Keys
k1, k2 = pow(y2, x1) % P, pow(y1, x2) % P
print(f"\nSecret Key For User 1 Is {k1}\nSecret Key For User 2 Is {k2}\n")
if k1 == k2:
        print("Keys Have Been Exchanged Successfully")
else:
    print("Keys Have Not Been Exchanged Successfully")
```

OUTPUT:

```
-(kali®kali)-[~/Documents/cnslab]
vi diffie.py
 —(kali⊕kali)-[~/Documents/cnslab]
s python3 diffie.py
Enter P: 23
Enter The Primitive Root Of 23: 9
Number Is Not A Primitive Root Of 23, Please Try Again!
Enter The Primitive Root Of 23: 3
Number Is Not A Primitive Root Of 23, Please Try Again!
Enter The Primitive Root Of 23: 4
Number Is Not A Primitive Root Of 23, Please Try Again!
Enter The Primitive Root Of 23 : 5
Enter The Private Key Of User 1: 4
Enter The Private Key Of User 2 : 3
Secret Key For User 1 Is 18
Secret Key For User 2 Is 18
Keys Have Been Exchanged Successfully
```

RESULT:

Thus, a python program has been implemented to demonstrate Diffie Hellman Key Exchange Algorithm.
